The Biological Basis of Language 1

Language is Species Specific :

What that means is:

members of the species language is likely to be part of the genetic makeup of So far scientist haven't found similar tendencies in other species.

Universal Grammar:

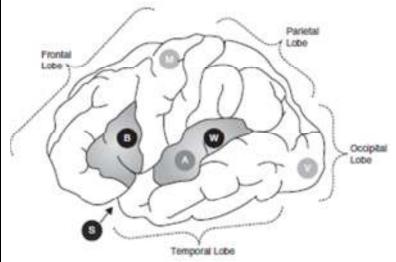

What we mean by that is:

languages of the world are similar because all humans have the same language capacities. However please note that the term Universal Grammar also has other implications.

The critical period :

Is there an age restriction on acquiring a first language? There is a very strong view that there is an age restriction.

Neurolinguistics:

Neurolinguistics is the study of the representation of the language in the brain.

Aphasia :

Aphasia is a language impairment linked to brain injury.

Broca's aphasia is also known as non-fluent aphasia.

Is characterized by halting, effortful speech; it is associated with damage involving *Broca's* area in the frontal lobe of <u>the left hemisphere</u>.

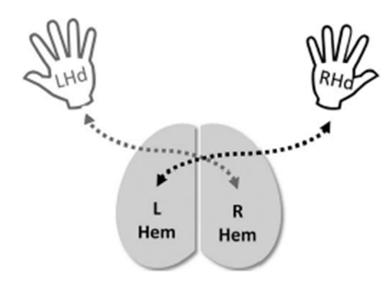

Wernicke's aphasia is also known as fluent aphasia.

Is characterized by fluent meaningless strings; it is caused by damage involving *Wernicke's* area in the temporal lobe of <u>the left hemisphere</u>.

The Biological Basis of Language 2

Left and Right Hemispheres :

language is *lateralized* :

That is: language function is located in one of the two hemispheres. Not all people are the same. Some have it on the in right, some in the left and some in both hemispheres.

But most people have it in the left.

Control of the body is contralateral :

That is: the left hemisphere controls the right side of the body and the right hemisphere controls the left side of the body.

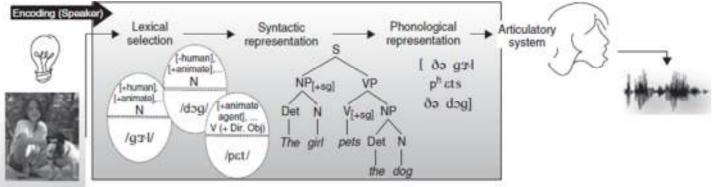

The *dichotic listening* experiment

In this experiment the participant is given two different inputs to each ear at the same time. Usually the participant reports what he/she heard in the right ear. This is called <u>the **right-ear advantage for language**</u>

LECTURE 9 The Speaker

Before We Speak

The production of a sentence begins with the speaker's intention to communicate an idea or some item of information. This has been referred to by Levelt (1989) as a **preverbal message**, because at this point the idea has not yet been cast into a linguistic form. Turning an idea into a linguistic representation involves mental operations that require consulting both the lexicon and the grammar shared by the speaker and hearer.

The diagram above discribes some processing operations, ordered left to right, performed by the speaker when producing the sentence *The girl pets the dog*. Production begins with an idea for a message (the light bulb on the far left) triggering a process of lexical selection. The capsule-like figures represent lexical items for the words *girl, dog, and pet, activated based on the intended meaning for the message;* these include basic lexical semantic and morphosyntactic information (top half) and phonological form information (bottom half). The tree diagram in the center represents the sentence's syntactic form. The phonetic transcription to the right represents the sentence's eventual phonological form, sent on to the articulatory system, which produces the corresponding speech signal. The different representations are accessed and built very rapidly and with some degree of overlap

What if the speaker speaks two languages?

Few adjustments need to be made to the working model in diagram above to account for production by people who speak two or more languages. We need to assume that a bilingual has two language-specific grammars, and a lexicon with language-specific entries, and we need to specify how these language-specific knowledge repositories are activated (or deactivated) – but that is all. When a bilingual is speaking in a **unilingual mode (only one language)**, only one of the grammars is consulted to build structural representations, and the active language's lexical entries are activated. When in a **bilingual mode** (when the bilingual's two languages are being used in the same conversation), access to both grammars and lexical items from both languages must be possible (Grosjean 2001).

Code-switching

One type of alternation between languages in bilingual speech is **code-switching**. **Code-switching is switching between two codes** (two languages, or two distinct dialects of the same language) within the same discourse. A switch can take place between sentences (*intersentential code-switching*). A switch can also occur within the same sentence (*intrasentential code-switching*), at clause boundaries, or at smaller phrasal boundaries. A third category, tagswitching, involves the insertion of frequently used discourse markers, like so, you know, I mean, etc.

Barrowing

Code-switching is not to be confused with barrowing. When a word from one language is incorporated into the lexicon of another language, The phenomenon is called **borrowing**.

LECTURE 10 The Speaker 2

Lexical Retrieval

Remember that speech begins with an idea in the speaker's brain.

Remember that the lexicon is a dictionary of all the words a speaker knows. A lexical entry carries information about the meaning of the word, its grammatical class, the syntactic structures into which it can enter, and the sounds it contains (its phonemic representation). A word can be retrieved using two different kinds of information: meaning or sound. The speaker retrieves words based on the meaning to be communicated and has the task of selecting a word that will be appropriate for the desired message. The word must also be of the appropriate grammatical class (noun, verb, etc.) and must be compatible with the structure that is being constructed.

It is most certainly not the case that the structure is constructed before the words are selected, nor are all the words selected before the structure is constructed. In fact, the words and the structure are so closely related that the two processes take place practically simultaneously. Ultimately, the speaker must retrieve a lexical item that will convey the correct meaning and fit the intended structure. This means that a speaker must enter the lexicon via information about meaning, grammatical class, and structure, only later to retrieve the phonological form of the required word. The hearer's task, is the mirror image of the speaker's. The hearer must process information about the sound of the word and enter his lexicon to discover its form class, structural requirements, and meaning.

tip-of-the-tongue phenomenon

the speaker knows the word but cannot retrieve it

A phenomenon in lexical retrieval that has fascinated psycholinguists for decades is the **tip-of-the-tongue phenomenon** (Brown and McNeill 1966; Aitchison 2003). A tip-of-the-tongue state occurs when the speaker knows the word needed but cannot quite retrieve it. It is a very uncomfortable mental state, and when people experience it, they might say "I've got that word right on the tip of my tongue!" What people experience during a tip-of-the-tongue state offers a glimpse into the steps involved in lexical retrieval. Typically, people have access to the meaning- based part of the lexical representation, but experience a tip-of-thetongue state when they fail to find a fully specified formbased representation (Bock and Levelt 1994). However, people typically know something about the word they are unsuccessfully searching for. They can often think of the initial or final sounds or letters, how many syllables it has, where primary stress is located, and even words that sound similar. People experiencing a tip-of-the-tongue state will often also perform gestures that are suggestive of the meaning of the word, though it is not necessarily the case that gesturing helps retrieval (Beattie and Coughlan 1999).

Usually lexical retrieval produces an

appropriate set of words required for the speaker's sentence.

Grammatical encoding

Levelt (1989) refers to the creation of sentence structure during sentence planning as *grammatical encoding*. For this the speaker must consult the internalized grammar to construct structures that will convey the intended meaning. Again, speech errors provide information about some of the characteristics of the representations that are constructed. We know, for instance, that words are represented as separate units. Speech errors like the ones below provide evidence for this:

Word exchange error

"I left my car in my briefcase".

"I left my briefcase in my car". Intended:

These examples illustrate a common type of error, **exchange errors; the** exchange units here are two words. **Word exchange errors never occur** between content words and function words and are usually limited to

А. В.

Said:

The Speaker 3

Creating agreement relations :

There is another class of errors, which has been studied extensively in English and several other languages, involving subject–verb agreement.

English requires that verbs and their subjects agree in number (and person).

Example:

a. The bridge close<u>s</u> at seven.

b. The bridge<u>s</u> close at seven.

Plural attraction :

When a plural feature intervenes between a singular subject and its verb error can occur. Example:

a. The time for fun and games are over.

b. The *illiteracy level* of our children *are* appalling.

Preservation error :

"I can't cook worth a cam".	Said:	Α.
"I can't cook worth a damn".	Intended:	В.

Sentence A above is an example of a preservation error.

In this example segment (in this case the /k/ of *can't*) *perseveres* and intrudes in a later word (so the speaker utters *cam rather than damn*).

Anticipation error :

"taddle tennis".Said:A."paddle tennis".Intended:B.Sentence A above is an example of an anticipation error.In this situation a speech sound that has not yet been produced (the /t/ of tennis) intrudes in an earlier word.

Segment exchange error :

"hass or grash".				Said:	A
					_

"hash or grass". Intended: B.

Sentence A above is an example of a segment exchange error. In this situation the exchange is between two phonological elements: *the final consonants in the two words*.

What does this tell us ?

Errors like the ones above demonstrate that there is a level of representation in which phonological elements are represented segmentally. Such errors are revealing about the psychological reality of linguistic representations before sound is produced. Errors like these – anticipation errors in particular – demonstrate that there is a mental representation containing the phonological form of a sentence, some time before a sentence is actually produced.

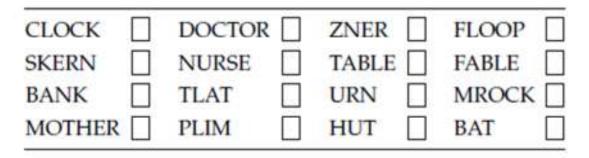

LECTURE 12 The Hearer

The hearer's task

The hearer's task is almost the mirror image of the speaker's task. First, using information from the acoustic signal, the hearer reconstructs a phonological representation. The hearer enters the lexicon using that phonological representation to retrieve the lexical items that match. This permits the hearer to recover the semantic and structural details of the words in the message.

post-access matching

After a word has been retrieved, its full phonological representation is checked against what has been heard. This is called **post-access matching.** If the match is good enough, the word is accepted as correct and the full phonological representation from the lexicon becomes the percept.

Impossible non-words and possible non-words

You probably wrote N next to six of the letter strings, and might have even noticed that you responded to three of them very quickly – TLAT, ZNER, and MROCK – and to the other three somewhat more slowly – SKERN, PLIM, and FLOOP. All six strings are non-words in English, but the first three violate the phonotactic constraints of the language. **Impossible non-words, like TLAT, ZNER, and MROCK, are** rejected very rapidly in a lexical decision task. It is as if the lexical retrieval system were carrying out a phonological screening of sorts, not bothering to look in the lexicon when the string is not a possible word in the language. In contrast, **possible non-words, like SKERN,** PLIM, and FLOOP, take longer to reject, as if the retrieval system conducted an exhaustive, ultimately unsuccessful, search for their entries in the lexicon.

The cohort model of lexical access

A word's **cohort consists of all the** lexical items that share an initial sequence of phonemes. According to the cohort model, acoustic information is rapidly transformed into phonological information, and lexical entries that match the stimulus phonologically are *activated*.

A word's neighborhood

A factor that affects retrieval times for words is **neighborhood density.** A word's **neighborhood** consists of all the lexical items that are phonologically similar. Some words have larger cohorts than others: the word *cot has many words that are phonologically similar to it, so it* is said to come from a dense neighborhood; in contrast, the neighborhood for a word like *crib* is less dense.

The language gene

The search for a genetic basis for language

The ultimate indicator of the biological nature of language would be the discovery of *the genetic basis of language*, as all aspects of human biology are directly encoded in our DNA.

Researchers began genetic investigations by conducting *pedigree studies*. These are studies that examine the heritability of a particular trait (or disorder) in several generations of a family.

Gopnik (1990, 1997) showed that members of over three generations of one family had suffered from specific language impairment (SLI), dyslexia, and other language disorders, indicating that genetic anomalies associated with language development can be inherited.

A major breakthrough came with the discovery by Lai and colleagues (Lai et al. 2001) of a specific gene, **FOXP2**, that was implicated in the language disorders of an extended family.

Members of the family exhibited symptoms like those of agrammatic aphasics: effortful and non-fluent speech, lacking in syntactic organization. Their grammar appeared to be broadly impaired; they had difficulty manipulating phonemes and morphemes and understanding complex sentences (Watkins, Dronkers, and Vargha-Khadem 2002). The disorder was attributable to a mutation of the **FOXP2** gene, which was transmitted by heredity.

The logic of all of this !

If a mutated version of a gene is responsible for language disorders, it is reasonable to infer that an intact version of that gene is implicated in normal language development and representation. It was suggested that a **"gene for language"** had been discovered.

However !

The **FOXP2** gene is associated with the development of other parts of human anatomy unrelated to language, including the lung, the gut, and the heart. It is also a gene that is not confined to *Homo sapiens; it is* also found in other mammals, including mice (Marcus and Fisher 2003).

While the relationship of FOXP2 to heritable language disorders is an exciting breakthrough, it is important to remember that it cannot be *the* gene for language.

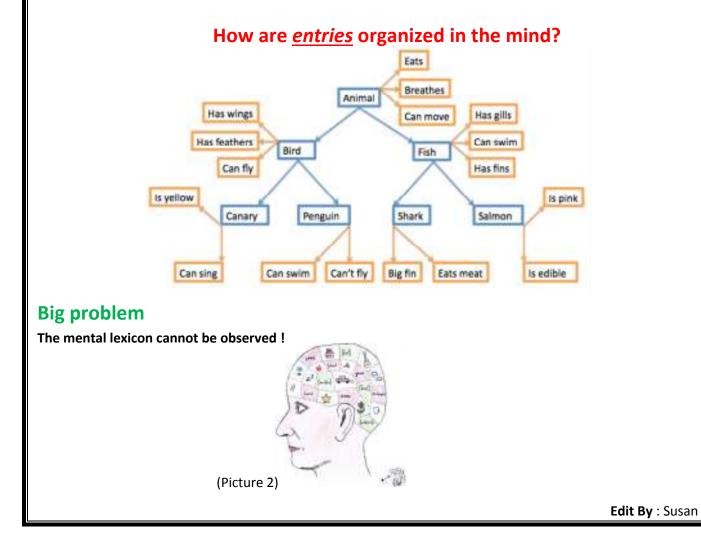

General Remarks

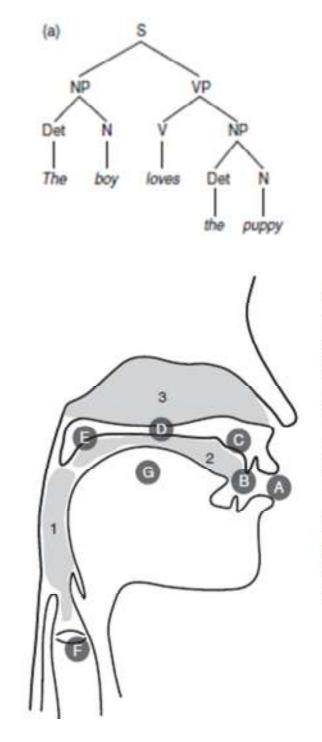

• What do psycholinguists study ?

Answer:

- A lot of things related to language. However, with a special concentration on **HOW** language is dealt with in the human brain or in other words how language is *processed*.
- How are words and word meanings represented in someone's mind?
- How are sentences composed in someone's mind at the time of speech?
- How are words and sentences and their meanings analyzed at the time of listening or reading?

S – Sentence (– Clause) NP – Noun Phrase VP – Verb Phrase Det – Determiner (– Article) N – Noun V – Verb

Articulators:

A. Lips (bilabial sounds)

- B. Teeth (labiodental and dental sounds)
- C. Alveolar ridge (alveolar sounds)
- D. Hard palate (palatal sounds)
- E. Velum, soft palate (velar sounds, and nasal/oral distinction)
- F. Larynx, vocal folds, glottis (glottal sounds)
- G. Tongue

Cavities:

- 1. Pharyngeal
- 2. Oral
- 3. Nasal

Best wishes for all VJ Designer Susan
